Plant Ecology

Reed C. Rollins

Lecture + Field Notes.

Introduction
Method and History
The plant
Environment
Interaction of Environment + plant.
a. Individual plant
b. Plant Communities.
Applications -

Oikos or affairs of the household = Ecology -
plant in relation to its environment.
plant identity necessary -
Ecologists borrow from other branches of Botany
as well as other sciences -
In plant ecology one must depend on
diagnoses - partially depends on familiarity
and general aspect. This is gained thru
systematic study

Plant Geography - distribution of plants over world.
Floristics - distribution of types of plants -
The distribution of a Genus for instance.
Vocabulary -
Ecology has two aspects -
1. Individual - Autecology
2. Community - Synecology

Ecology has been long been a na

Von Humboldt - 1800 approx - Cosmos.

1895 Warming - Danish - First text -

1. Dicsmuss factors etc - (attention focused on on small area)

1898 - Schimper, A.F.W.

Plant Geography on a physiological basis.

Made an attempt to tie up world vegetation with

Phytogeography of Nebraska 1898 - work engineered by students at Nebraska -

Pound & Clements -

always concerned with water - pattern in soil also worked with grasses - detail analysis of grass land - stressed importance of statistics. Natural since grasses are so small - analysis not so important in forests -

Cowles - at Chicago - 1898

Worked at land & sensed erosion & deposites. On boundary between grass & forest - was impressed with physiographic change -

Modifications caused by

1. Wind
2. Water
3. Time.

Chicago school depended upon

Scandinavians & Swiss made great progress in study of Ecology -

Sources

Textbooks -

1. Weaver & Clements -
2. A Textbook of Botany Chicago - Cowles - Autecology
3. Tansley & Clip - Aims & methods in the study of vegetation - ~~for~~ Tansley - professor of botany at Oxford -
4. Colorado plant life - Ramaley -
5.

Journals -

Ecology -

— ·· — ·· — ·· — ·· — ·· —

Application

Ecologist has more or less of a synthetic view point. Analysis - then syntheseizes or puts together - problems must be worked out in the field - not as precise as physiology for instance -

little application in this country - rather widely used abroad. Ecology rapidly touches social & political ramifications -

what causes plants of the same type to be retarded in localized areas? Local factors i.e. Snowdrift; clump of trees, angle of exposure to sun etc - Edaphic factors in other words.

There is a reciprocal action between plants and their environment

Physiographic factors play upon the nature of plant growth as well as the seasonal growth - physiographic factors may be aided or counteracted by other factors such as moisture, Biotic factors etc.

Local factor may delay plant growth –
edaphic factor
1. Snow melts earlier in certain
2. plant affect environment = Environment
effects plants.

weeds = dry situation
Valariana
polygonum
Eriogonum
yarrow

wet situation – spring
onion
saxifrages
cinquefoil
Buttercup –

Bunn 1867 – north of camps
Biotic factor – Grazing.
Bunn –
Erosion –

plants come in because of adaptability to
physiographic factors condition.
Hydrophytes

Physiography = Form or nature of the earth's crust.

annuals reproducing entirely by seed, must of necessity start in bare ground (devoid of competition

The Picea - Abies community seems to be the culmination of the succession at around 9 to 10 thousand feet in the W. Boreal. North of camp a secondary succession is in progress.

On bare rocks lichens are the pioneer community. They break up rocks in two ways

1. Dissolution with organic acids
2. Mechanically by contraction when wetted,

Picea sitchensis
Spruce

Pinus contorta
Lodgepole pine

Pinus ponderosa
Ponderosa pine

Pinus monticola
White pine

Pinus lambertiana
Sugar pine

Pinus jeffreyi
Jeffrey pine

Abies concolor
White fir

Abies magnifica
California red fir

Abies grandis
Grand fir

Abies amabilis
Pacific silver fir

Abies nobilis
Noble fir

Tsuga heterophylla
Western hemlock

Tsuga mertensiana
Mountain hemlock

Pseudotsuga taxifolia
Douglas fir

Libocedrus decurrens
Incense cedar

Thuja plicata
Western red cedar

Chamaecyparis lawsoniana
Port Orford cedar

Juniperus occidentalis
Western juniper

Taxus brevifolia
Western yew

Range & Variation | in
1. Woody & herbaceous
2. Suffering
3. plasticity of structure & plants
a. Environmental - influence
1. produces
b. Developmental - [illegible]
c. Genetic variation - not plastic
d. Mutation - sport
extends range of plants -
Each species or variety is adapted to live within a certain range of conditions within this range the optimum conditions may be found. The further away from the optimum conditions the more the plant must be protected.
This optimum is an interaction of several factors - moisture, temp., soil conditions etc.
An inherited tendency allows plants to vary within limits

2147 ft per step

2147 ft per step.

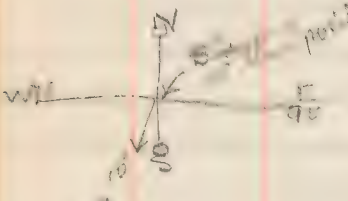
Reading the Prentice Compass

Variation in Med. Bowman 15½ E. of
True north

Variation - angle between true north
and magnetic north

declination - angle in vertical plane
dip - towards magnetic pole



1. Always read opposite the point
and to the right
2. Before reading the number of degrees
read between which figures and
which is the north point of the
needle lies.
3. Read degrees.

1. Hold for an object in hand and level with the universal bubble.
2. Turn front sight half up.
Adjust head until object can be seen in the mirror.
The sights are probably crossed - move head to one side or the other until sights are parallel.
Swing the body until the sights are on the object.
Read.

July 10, 1931

Climate is not fixed entirely - changes are occurring.

Valleys are particularly good for ecological studies.

Marine [illegible] plains + mountain vegetation.

Flood plain vegetation - willows - alder

Mesic in valleys

South slopes = xeric - (pines)

North slopes more or less mesic

Spruce + fir mixed in with pine

Native vegetation disturbed.

a. Secondary communities

b Relicts (relicts)

Old flood plains on down from

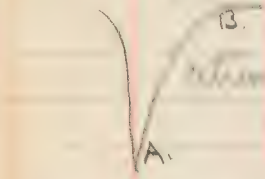
phyiographic change causes



Development usually tends to make ... more uniform. A peneplain is an expression of diminished differences. Vegetation has a profound effect on topography and habitat factors.

4. Soil development:

Soil is result of long slow change addition of humus & dead plant material. One of the practical effects is to increase the water holding capacity of the soil.

plant succession.)

1. Profound effect on distribution of plants
2. Short cycles of climate at points of extreme ... not well marked in most plants

3. genuine succession in terms of climatic phenomena as factor.
